In biochemistry and other classes of polymeric compounds, an assumption of proportionality between the UV absorbance and the number of repeating chromophore units is usually made. The studied macrocycles - hemicucurbiturils (HC) - are also synthesised via a polymerization reaction, in which a complex mixture consisting of cyclic and linear homologues and isomers is formed. The analysis and separation of such a mixture is challenging.

We have synthesized and characterised enantiomerically pure hemicucurbiturils [1-4] (see Figure 1A), which are notable for their capability to bind anions, and additionally 6-membered achiral diastereomers of cyclohexano-hemicucurbit[6]urils (cycHC[6]) (Figure 1B).

Figure 1. A) synthesis of (all-*R,R*)-cyclohexano-hemicucurbituril homologues and B) synthesis of (all-*cis*)- and (*i-cis*)-cyclohexano-hemicucurbit[6]urils

In this work we show that compounds (macrocycles, oligomers and monomers) consisting of the same building blocks have some unexpected spectroscopic peculiarities. Observed phenomenon should be considered also in quantification of other classes of polymeric macrocycles.
